

WebSpy's flagship data capture software, WebSpy Sentinel, records the activity of multiple protocols on your network, including web, secure web, email, telnet, FTP and POP3. Sentinel can also be configured to capture the full content of these protocols.

Sentinel works in conjunction with Analyzer, Vantage and Live to provide a complete Internet monitoring solution.

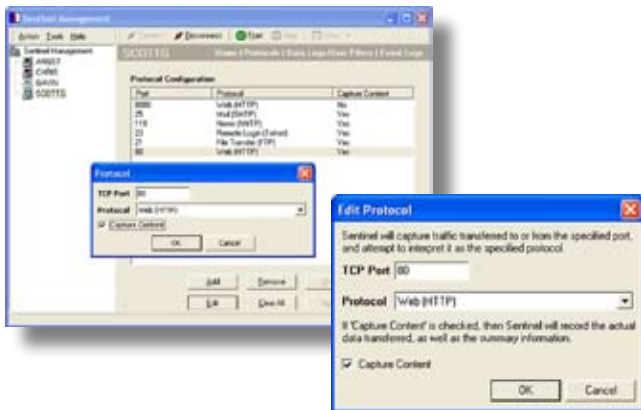

Full content data capture

Sentinel will not only store URLs but has the ability to capture full web content and full email messages. Full content can be viewed in any WebSpy Analyzer and Vantage applications by drilling down to Individual Hits on the Summaries screen.

Sentinel can also be configured to log only low-level data without content, such as only the names of web pages visited without content, or the subject lines of emails without the body of emails.

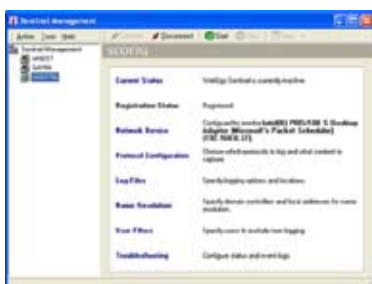

Multi-protocol data capture

Sentinel can capture and log all email, web, secure web, newsgroup, telnet and POP3 information.

Separate service & management console

A multi-component system allows multiple installations of Sentinel Service to capture all Internet traffic. The management console enables configuration of all Sentinel services from one computer.

Easy Installation

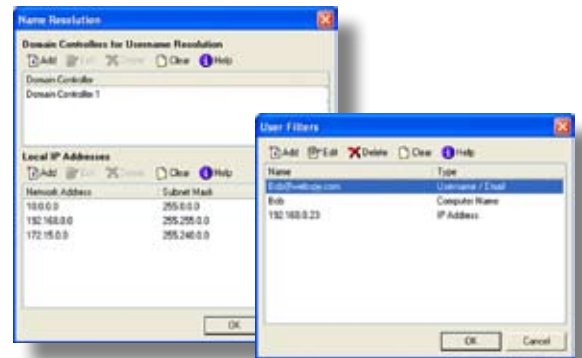

Sentinel does not need to be installed on every PC on the network. It is designed to be installed in one central location.

Integrates with Analyzer & Live

Import Sentinel log files into WebSpy Analyzer for reporting and analysis. Sentinel can also be used with WebSpy Live to generate alerts in real time when users breach your Internet or email usage policies.

Username resolution

Sentinel enables accurate monitoring of employees by logging resolved usernames as well as IP addresses. You can improve Sentinel's performance and efficiency by specifying the networks you want Sentinel to resolve usernames for (defined by network and subnet masks).
